Cardoso App

Product Update

08 Nov 2026

This update (v2026.5.13) focuses on speed and reliability. The app loads faster across the board — pages without charts start quicker, the dashboard sales cards respond faster, and the BAT Cross-Reference panel scrolls smoothly even with many rows. Customer syncing and the nightly inventory sync are lighter on resources, and four reliability fixes ensure that manual flags, auto-flags, dashboard data, and force-resync all behave correctly.

Improvements

IMPROVED

Faster page loads and a more responsive app

Several performance improvements make the app noticeably quicker to use. Pages that do not include charts now load faster. The reporting dashboard's sales cards respond more quickly. Status updates across the app share a single background check rather than each running independently, reducing network traffic and keeping the interface snappier.

BAT Cross-Reference panel scrolls smoothly

The Cross-Reference panel in BAT reconciliation now renders only the rows in view, so it stays smooth and responsive even when it contains a large number of entries.

Customer sync is lighter on resources

During data syncing, customers are now written in smaller batches with brief pauses in between. This keeps the application responsive while a sync is running and prevents large syncs from briefly freezing the interface.

Nightly sales sync is faster

The nightly sync now updates only the sales months that have changed, instead of rebuilding the entire history every night. This makes the sync noticeably faster and reduces the work the app does in the background each night.

Hub AR data refreshed efficiently

Accounts receivable document summaries and invoice-profit totals on the hub are now recalculated at most every 30 minutes, preventing unnecessary repeated calculations while keeping figures current.

Fixes

FIXED

Manual flag changes are correctly recorded

When you manually change a customer flag, it is now correctly recorded as a manual override — ensuring the flag stays in place and is not silently overwritten by an automatic rule on the next sync.

Auto-flags clear when their rule is disabled

Disabling the last active rule that was automatically flagging a set of customers now correctly removes those auto-flags. Previously the flags would remain even though no active rule was responsible for them.

Dashboard sales cards always load correctly

The sales summary cards on the reporting dashboard now warm up the underlying data before displaying it, so they show correct figures even after a fresh setup or when the rollup data has not yet been built.

Force re-sync re-pulls inventory from Sage

When a force re-sync is triggered from the hub, the system now correctly clears cached source tokens so that all inventory data is freshly fetched from Sage rather than using a previous pull.
