Product Update

9 Nov 2026

This update (v2026.5.15) focuses on accuracy, reliability and visibility across Collections, the Hub, Backups and Insights. Collections no longer marks accounts as 'Paid in full' based on a sync-cleared balance; credit invoice aging is now calculated in South African days; and the hub sends same-day customer changes immediately. Alerts now show their full text with an Acknowledge button, and a new alert fires when a customer sync connection goes stale. At-risk customer detection in Insights is approximately 75× faster.

New Features

NEW

Alert when a customer sync connection goes stale

A new alert fires automatically when a customer data connection has not synced within its expected window. Stale branches are now flagged proactively rather than discovered when a figure looks wrong.

Alerts now show their full text with an Acknowledge button

Each alert in the Insights feed now displays the full alert message, giving you the detail needed to act without navigating away. An Acknowledge button lets administrators mark an alert as seen. Alert text and the Acknowledge action are shown only to administrators, keeping the view clean for other users.

Improvements

IMPROVED

At-risk customer detection in Insights is ~75× faster

The query that identifies at-risk customers has been rewritten. It now completes in roughly 46 ms instead of 3.6 s, so the Insights feed loads and refreshes almost instantly.

Sync Now and Sync All report what actually happened

Running a manual sync now shows a clear summary of what each run did — which customers were updated, which were skipped, and any that could no longer be found in Sage. If a sync fails, it retries the connection automatically before giving up.

Fixes

FIXED

Collections no longer labels accounts as 'Paid in full' incorrectly

When a customer's balance was cleared by the nightly data sync rather than by an actual payment, Collections could mark the account as 'Paid in full'. The logic now correctly distinguishes a sync-cleared balance from a genuine receipt. Historical records mislabelled in earlier versions have been corrected automatically. Additionally, assignments are now closed when a customer is removed from Sage, so the worklist stays up to date.

Credit: invoice ages are now calculated in South African days

Invoice ages in the Credit area were calculated one day shorter than the correct South African (UTC+2) day boundary. Ages now reflect the correct local date, so overdue status and aging buckets match what you see in Sage.

- **Removing a site from the hub now clears all of its data**

  When a site was removed from the hub, some customer and reporting records were not deleted. This has been fixed, and any stale data left by previously removed sites has been cleaned up automatically.

- **Same-day customer changes now reach the hub**

  Customer records updated in Sage on the same day as a hub sync were sometimes missed. The hub now uses the correct cutoff time so that all changes made on the day of the sync are included. Customers who have been removed from Sage also have their balances cleared promptly.

- **Backup pruning never removes the most recent verified backup**

  A logic gap could cause the backup prune to delete the newest verified backup if it fell outside the retention window. The prune now always keeps the most recent verified copy, and remembers which backup was last verified even after the job history is cleared.

- **An incomplete backup no longer appears healthy**

  A backup file cut off mid-write (for example, by a system interruption) could previously pass the health check and be reported as a good backup. Incomplete files are now detected and marked as failed.

- **"Sage down for N min" counts from the actual start of the outage**

  The health indicator showing how long Sage has been unavailable was measuring from the wrong reference point, making outages appear shorter than they were. It now counts from the first moment connectivity was lost.

- **Inventory sync now reports failures correctly**

  When the inventory rollup or vendor-refresh step failed during a sync, the job was incorrectly recorded as successful. Failures are now reported accurately in the Job Runs log.
