

This update (v2026.5.11) delivers a major upgrade to the Hub Backups page — now a scannable fleet table with off-site Kopia restore built in — plus a new sidebar health strip for at-a-glance subsystem status, richer Ctrl+K command palette actions, and filtering and export tools on two log screens. A set of reliability fixes tighten local backup pruning, improve Kopia connectivity diagnostics, harden monthly export stability, and correct Hub copy status accuracy so nothing is shown as healthy when it shouldn't be.

New Features

NEW

■ Hub Backups redesigned as a fleet table with off-site restore

The Hub Backups page has been completely redesigned as a scannable fleet table. Every site's local, SQL Server, and off-site Kopia backup states are now first-class columns on a single screen — no need to click into each site separately. Head-office users can also browse the off-site Kopia snapshot repository directly in the app (with a link to the Kopia UI for deeper detail), and initiate a restore without leaving Cardoso: stage a snapshot, download it, and push it to the live site in one flow.

■ Sidebar health strip

A compact health strip now appears in the sidebar, showing the status of key subsystems — such as backup and data sync — at a glance. Named subsystem outcomes are displayed in a 2×2 grid so you can see at a glance whether everything is healthy without navigating away from your current page.

■ Command palette — actions and settings deep-links

The Ctrl+K command palette has been extended beyond page navigation. It now supports direct actions and can deep-link into specific settings tabs, reducing the steps needed to reach configuration screens. Quick entity search is also wired in so you can jump to a specific record directly from the palette.

■ Log screens — filter, column picker, and CSV export

Two log screens now include a DataTable toolbar with a live search filter, a column visibility picker to show only the fields you need, and a one-click CSV export of the current view.

Improvements

IMPROVED

■ Hub copy status stays accurate while data loads

The hub-copy backup status no longer shows 'never synced' while the underlying query is still resolving. A stalled hub copy is also now aged correctly — it no longer shows as green (healthy) when the last successful pull is overdue.

■ Inventory data loads without freezing the app

The sales-rollup rebuild — which runs during inventory syncs — is now broken into smaller yielding steps. Large datasets no longer cause the application to pause or become unresponsive, and concurrent warm-up requests are handled cleanly without duplicated work.

- **Local backup pruning now actually runs — keeps 3 days, never zeros out**

A bug was preventing the local backup prune from executing at all, which could allow old backup files to accumulate indefinitely. Pruning now runs correctly, retaining the most recent 3 days of backups and removing older ones. The prune summary is also returned correctly and filename matching has been tightened.

- **Kopia backup agent reports the real connection error**

When the Kopia off-site backup agent fails to connect to the repository, it now logs the actual reason rather than a generic exit code, making connectivity problems much easier to diagnose.

- **Monthly export is freeze-proof and alerts when a period is missing**

The automated monthly export process is now protected against freezes during generation, and exports are serialised per period to prevent conflicts. An alert is raised automatically if a month's export is found to be missing, so nothing slips through unnoticed.

- **Hub Backups blocks restore from incomplete snapshots**

The Hub Backups page now prevents initiating a Kopia restore from an incomplete snapshot. Only fully verified snapshots are offered for restore, eliminating the risk of pushing partial data to a live site.
